

Volty U1

Financial Dashboard

24-month operating model across Conservative, Base, and Optimistic scenarios. Print edition shows the Base case; the interactive scenario switcher exists only in the web dashboard.

MODEL	v1.6.1
PRINTED	August 2026
PREPARED BY	Han Hoang, Co-Founder, Head of Investment and Strategy
STATUS	Confidential, for invited recipients only

Read this first: the model behind this dashboard has not been re-anchored to the current plan.

What is current. Unit economics, the cost stack, the working-capital cycle, tax treatment, and the OPEX and headcount structure all reconcile to model v1.6.1 and stand on their own. Use them.

What is stale. Every projection below is calculated from an April 2026 start on a \$1.0M capital structure (\$250K bridge at a \$10M cap plus \$750K seed at \$10M pre-money) released in three tranches across April, July, and October 2026. That structure is superseded. The company is raising \$500K at a \$5M pre-money valuation, targeting September 2026, alongside a separate 200-unit customer-financed pre-sale that funds production without dilution. The Volty U1 launches September 2026.

What that means. Revenue timing, cash curves, minimum-cash points, break-even month, the tranche schedule, and the post-seed cap table are keyed to the superseded structure and are not the current funding plan. Re-anchoring requires re-running v1.6.1 from a September 2026 launch on the new capital stack. That has not been done, and nothing on this page simulates it.

About this print edition. The web dashboard is interactive: it switches scenarios, and its charts respond to hover. Neither survives a PDF. Every chart here is rendered statically on the **Base case**; Conservative and Optimistic figures remain available in the scenario tables. Chart values are drawn from the same v1.6.1 arrays the web page uses, so the two agree.

Executive Summary

A scenario-driven view of the **Volty U1** business case: what the model is, what it assumes, and where the numbers land. Use the four headline metrics below as the at-a-glance read; every section that follows drills into one driver of these outcomes.

This dashboard is the live financial model behind Volty U1, NUEN MOTO's delivery-optimized, multi-network electric utility motorcycle.

Its purpose is to translate a single product strategy (a capital-light, B2B-first fleet play built around cross-compatible battery swapping) into numbers an investor or fleet partner can interrogate. It runs three scenarios (Conservative, Base, Optimistic) across unit volume, growth rate, pricing, and OPEX, and shows the downstream effect on revenue, break-even timing, gross margin, working capital, and investor returns.

The headline read in the Base case: roughly **15,000 units over 24 months**, around **\$22.9M of cumulative revenue**, EBITDA turning positive in **Q4 2026** and full break-even by **month 14**, on a margin that arrives with volume: roughly 6% blended at mid-scale, expanding to about **26% blended at full scale**. The model is deliberately conservative and explicit about its two pressure points, BOM cost sensitivity and per-unit working capital, both stress-tested in later sections. Every figure on this dashboard reconciles to model v1.6.1; the section footers name the source sheet.

BRIDGE-PHASE CAPITAL

\$350K

Superseded structure. Current raise is \$500K at \$5M pre-money.

24-MO REVENUE (BASE)

\$22.9M

~15,000 units across 24 months

BREAK EVEN (BASE)

Month 14

~4,300 cumulative units, 24-month fixed-cost basis

GROSS MARGIN (BASE, AT SCALE)

26%

Blended; ~6% at mid-scale, margin arrives with volume

Actuals as of August 2026

Everything else on this page is forecast. This block is not, and it is deliberately unfilled. A dashboard that projects five years of revenue without stating current cash reads as a pitch rather than a model. These fields are owned by the finance close, not by this document, and must be entered from the ledger before the page is circulated.

CASH ON HAND (ACB, USD + VND)

TOOLING COMMITTED TO DATE
To be entered

Why this is blank rather than estimated. Every other number on this page is traceable to a model sheet. An estimated cash balance would not be, and an investor who later reconciles it against the bank statement will discount the sections that are accurate. Blank with an owner is stronger than approximate without one.

Key Assumptions (Control Panel)

Every driver behind the numbers, by scenario, so nothing downstream is a black box. These mirror the model's Assumptions & Inputs and Scenario Analysis sheets; items still marked for confirmation in the model are subject to final Tier-1 supplier quotes.

DRIVER	CONSERVATIVE	BASE	OPTIMISTIC
Monthly unit growth (post-pilot)	8%	15%	25%
Fleet price per unit	\$1,300	\$1,200	\$1,200
Retail price per unit	\$1,500	\$1,500	\$1,500
All-in cost per unit at scale	\$1,019	\$967	\$904
Cumulative units, month 12	1,000	5,000	15,000
Cumulative units, month 24	5,000	15,000	30,000
Gross margin at scale (blended)	25%	26%	30%
Accessories attach rate (AOV \$250-300, 70% GM)	25%	40%	55%
Service subscription (\$15/mo, 50% GM)	20%	30%	45%
Average monthly OPEX (24-mo)	\$46.4K	\$73.3K	\$98.6K
CAC per unit	\$25		
Fixed program costs	\$420K tooling (\$20K pilot + \$400K scale) + \$27K testing & certification (incl. \$25K Vietnam Register)		
Working capital terms	50% customer deposit at PO, NET 30 balance, 60-day production lead, 50/50 supplier terms (all confirmed inputs)		
Funding tranches in the model	Apr 2026: \$250K bridge · Jul 2026: \$550-600K · Oct 2026: \$150-200K (milestone-gated)		

Source: Assumptions & Inputs, Scenario Analysis, and Working Capital Cycle sheets, model v1.6.1. BOM excludes batteries; batteries are carried by the BaaS partners.

Financial Scenarios

Toggle between the three cases to see how growth assumptions cascade through the model. **Conservative** (8% monthly growth) is the downside guardrail, **Base Case** (15%) is the planning scenario, and **Optimistic** (25%) is the upside if fleet conversions land early. The four metrics and both charts below update with your selection.

MONTH 12 REVENUE	MONTH 24 REVENUE	CASH POSITION, MONTH 24	GROSS MARGIN %
\$4.4M	\$22.9M	\$7.3M	26%

24-Month Revenue Projection

Cumulative Cash Position

Cash position is investment-inclusive (tranches Apr / Jul / Oct 2026). The Base case dips ~\$26K below zero at month 6 ahead of the October tranche; the raise buffer exists for exactly this window. Detail in Runway & Minimum Cash below.

Runway & Minimum Cash

The question every investor asks first: when could this run out of money? The cash curve above is investment-inclusive, so the honest risk is not the end balance, it is the **minimum cash point** between tranches. This section shows it, by scenario, with no smoothing.

MIN CASH, CONSERVATIVE (M11)	MIN CASH, BASE (M6)	MIN CASH, OPTIMISTIC (M8)
+\$5.8K	-\$26.2K	-\$50.9K

What this means. As scheduled (\$250K in April, \$550-600K in July, \$150-200K in October), the 24-month plan runs to a razor-thin minimum: the Conservative case bottoms at **\$5,784** of cash in month 11, and the Base and Optimistic cases briefly dip **below zero** (months 6 and 8) ahead of the October tranche, because faster growth consumes working capital faster. Tranche timing, not total capital, is the binding constraint.

Zero-revenue runway. On the bridge-phase capital of \$350K (\$250K bridge plus \$100K founder capital), at the pre-revenue burn of roughly \$40K/month (OPEX plus facility service), the company has about **8 to 9 months** of runway before any vehicle revenue. First vehicle cash lands in month 9 (December 2026) in all three scenarios.

How the dips are covered. The \$1.0M plan carries about \$95K of explicit contingency, and Han Hoang's \$100K founder capital sits alongside the bridge, outside the raise, in exactly the window where the dips occur. The alternative is equivalent: release part of the October tranche earlier. Either way, the gap is identified and covered, not discovered later.

5-Year Financial Revenue Projections (2026-2030)

Reading the ramp: Years 1-2 are the pilot-to-scale window the 24-month model covers in detail. Years 3-5 extend the trajectory as fleet partnerships convert into recurring volume and HCMC's gasoline ban for delivery/ride-hailing accelerates demand. Figures are illustrative annual projections, not committed orders.

Unit Economics & Pricing

The per-unit P&L at scale (Base scenario, 15,000 units). An all-in **\$967 build cost** against a **\$1,200 fleet price** leaves \$233 of fleet gross profit per unit; the 50/50 fleet-retail blend at **\$1,350** carries the margin to roughly **26%**. The Conservative case prices fleet at \$1,300 on a \$1,019 cost. The doughnut shows what dominates cost: BOM is ~93% of it,

which is exactly why the BOM stress test later matters so much. Margin is volume-dependent: at mid-scale (1,000 to 5,000 units) blended margin is only ~6%, which is the honest reason the model pushes to full production quickly. Source: Unit Economics and Scenario Analysis sheets, v1.6.1.

Pricing & Margin Scenarios	
Fleet Price (Base / Conservative)	\$1,200 / \$1,300
Retail Price (per unit)	\$1,500
Blended Selling Price (Base)	\$1,350
Gross Margin/Unit (Fleet, Base at scale)	\$233 (19.4%)
Gross Margin/Unit (Blended, Base at scale)	\$383 (~26%)
GM% at scale: Cons / Base / Opt	25% / 26% / 30%

A fourth revenue line exists and is not in these numbers. NUEN MOTO is negotiating a 15% share of gross battery subscription revenue on deployments it originates. The term sheet with Power-GOGO has been produced and is not executed, so no revenue from it appears anywhere in this model, in any scenario. That is deliberate: an unexecuted term sheet is not a revenue line.

The reason it matters is asymmetry, not upside. A battery network that owns the subscription captures roughly ten times the per-unit lifetime economics that the vehicle sale earns. Every unit delivered without an origination share hands that spread away permanently. If the share is executed, it is high-margin recurring revenue layered on an installed base the company already sold; if it is not, the model below is what the business is, and the hardware margin has to carry it alone.

Break Even Analysis

When the business stops burning cash, by scenario. Break-even ranges from **month 10** (Optimistic, ~3,450 units) to **month 18** (Conservative, ~4,325 units), with the Base case at **month 14** and ~4,300 units. Units are measured against 24-month fixed costs (\$420K tooling, \$27K certification, plus cumulative OPEX) at vehicle-only contribution margins of \$296 to \$371 per unit; counting accessory and service revenue, the all-revenue contribution margin is \$503/unit and the hurdle drops to ~2,550 units. The spread is driven almost entirely by how fast monthly volume compounds, shown in the chart on the left and the unit/month detail on the right.

Break Even By Scenario

Scenario Comparison

CONSERVATIVE (8% MONTHLY GROWTH)

Break Even Month	18
Break Even Units	~4,325

BASE (15% MONTHLY GROWTH)

Break Even Month	14
Break Even Units	~4,297

OPTIMISTIC (25% MONTHLY GROWTH)

Break Even Month	10
Break Even Units	~3,446

Quarterly P&L Summary (Base Case)

The classic table, straight from the model's Profit & Loss sheet. EBITDA turns positive in **Q4 2026** in the Base case (Q1 2027 Conservative, Q4 2026 Optimistic). Depreciation runs \$17.5K/month (tooling and certification amortization). Note a timing defect carried from the model: this charge begins in Q2 2026, but the \$400K of scale tooling it amortizes is not committed until Q4 2026. The model depreciates an asset before it exists, which overstates the pre-revenue loss and understates later-period depreciation. Correct on the next model run.

\$K	Q2'26	Q3'26	Q4'26	Q1'27	Q2'27	Q3'27	Q4'27	Q1'28	24-MO TOTAL	
Revenue	0	0	726	3,666	4,485	4,584	4,683	4,782	22,926	
COGS	0	0	492	2,479	3,018	3,067	3,117	3,166	15,339	
Gross Profit	0	0	234	1,187	1,467	1,517	1,566	1,616	7,586	(33% of rev)
OPEX	130	172	186	243	257	257	257	257	1,760	
EBITDA	(130)	(172)	47	944	1,210	1,259	1,309	1,358	5,826	
Net Income (pre-tax)	(183)	(225)	(5)	892	1,158	1,207	1,256	1,306	5,406	

Gross margin on this table runs above the per-unit blended figure because accessory (70% GM) and service (50% GM) revenue is included. Source: Profit & Loss sheet, v1.6.1.

Tax: Vietnam CIT, Applied Conservatively

Corporate income tax is in the model, not hand-waved. Standard **20% Vietnam CIT** is applied with a 5-year NOL carryforward; the preferential 10% high-tech rate and tax holidays are **not** assumed, keeping the model conservative.

CIT RATE APPLIED	FY2027 CASH TAX (BASE)	FY2027 EFFECTIVE RATE
20%	~\$175K	~11%

Pre-2027 losses build an NOL pool that shields roughly \$190K of 2027 taxable income. FY2027 accrues ~\$299K of CIT on ~\$1.6M of taxable income, with cash payments lagging about 30 days, so cash tax paid in FY2027 is ~\$175K, an effective ~11% against the nominal 20%. If the high-tech designation is granted (10% for 15 years plus holidays), every after-tax figure improves; nothing in this dashboard depends on it. Source: Tax & CIT Schedule sheet, v1.6.1.

Operating Expenses & Headcount

How the cost base grows as the team scales. Payroll starts at a lean **\$24K/month Phase 0 team** inside a **\$34.7K/month total fixed OPEX baseline** (rent, utilities, S&M, logistics, insurance, legal), stepping up in hiring phases tied to commercial milestones. In the Base case total OPEX averages **~\$73K/month** over 24 months and ends near **\$86K/month** as S&M scales with revenue (\$2.5K flat, then 2%, then 4% of revenue). The combo chart stacks spend by category against headcount (right axis); the mix and phase charts below show where the money goes and when people are added.

PHASE 0 PAYROLL / TOTAL OPEX

\$24K / \$34.7K/mo

MONTH 24 OPEX (BASE)

~\$86K/mo

HEADCOUNT: START → M24

10 → 30

S&M AS % OF REVENUE

2-4%

OPEX Mix at Month 24

Headcount by Hiring Phase

Phase-based hiring: Phase 0 (\$24K payroll, 10 roles incl. blended contractors) → Phase 1: +4 roles (Jul 2026, +\$4.4K) → Phase 2: +9 roles (Oct 2026, +\$13K) → Phase 3: +7 roles (Oct 2027, +\$12K). Hiring is gated to commercial traction, not calendar.

The sensitivity this model does not run: launch slip. Every projection depends on the Volty U1 launching in September 2026 and first deliveries following in Q4. There is no scenario in v1.6.1 for a slip, which makes the single largest schedule risk in the plan invisible on this page.

The structural read, pending a model run: a one-quarter slip does not change unit economics, break-even units, or the working-capital gap per unit, because none of those are time-dependent. It moves break-even month out roughly one-for-one, extends pre-revenue burn by a quarter against a fixed OPEX base, and pushes the fleet operating data that the next raise depends on into a later window. The exposure is runway and financing sequence, not viability. **Quantifying it requires re-running v1.6.1 with the start date shifted; that has not been done.**

Working Capital & Cash Cycle

The hidden cash trap of a hardware business. Even profitable units tie up cash because suppliers are paid before customers settle in full. The timeline on the left shows a **~\$478 per-unit gap** opening between day 60 and day 95. At 1,000 units/month that's a **~\$478K facility** requirement, which the mitigation strategies are designed to shrink.

Cash Conversion Cycle (Per Unit)

Day 0: Customer 50% deposit received	+\$675
Day 3: 50% supplier deposit paid	-\$479
Day 60: Supplier balance paid in full	-\$479
Day 95: Customer balance collected (NET 30)	+\$675

Peak Outflow, Day 60 to 95 (per unit)

~\$478

Working Capital Requirements by Volume

@100 units/month	~\$47.8K
@500 units/month	~\$239K
@1,000 units/month	~\$478K

Mitigation Strategies: ACB facility (bank line backed by signed POs), increased customer deposits (60-70% on new agreements), negotiated supplier credit (NET 30 post-delivery for established relationships).

The Investment Ask

The raise in one place: **\$1.0M total**, split into a **\$250K Bridge** for immediate use (converting at a \$10M cap) and a **\$750K Seed** at a \$10M pre-money valuation. A founder capital contribution from Han Hoang sat alongside the bridge, outside the raise. It was priced at the earlier founder-rate basis, not the investor basis, and the amount requires confirmation against the cap table before it is quoted to any investor. This section covers what the capital buys, how it is spent, and what an optimistic next round (Series A in 2030) would look like for the people who come in now.

TOTAL ASK	BRIDGE (IMMEDIATE)	SEED @ \$10M PRE
\$1.0M	\$250K	\$750K
POST-MONEY		
~\$11.0M		

The ask is \$1.0M to take Volty U1 from a validated pilot to early production, with \$100K of founder capital committed alongside it.

This is not a capital-heavy infrastructure bet. The battery-swap networks fund the swap stations; this raise funds vehicles, homologation, and the working capital to fulfill orders. It is sized to convert demand that already exists into revenue, then hand off to operating cash flow and a later growth round.

Converts the pipeline

Funds the pilot and first production runs. Under the current plan the near-term block is 200 units, financed by customers rather than by this capital.

Capital-light by design

Infrastructure cost sits with the battery networks, not NUEN MOTO. Multi-network compatibility keeps the fleet contract with NUEN MOTO and keeps every battery network replaceable, rather than feeding units into an ecosystem someone else controls.

Regulatory timing

HCMC's gasoline ban for delivery and ride-hailing creates a hard deadline that pulls fleet demand forward and rewards the first credible electric utility option.

Early entry price

The Seed comes in at a \$10M pre-money; the Bridge converts at a \$10M cap plus 6% accrued interest, so the cap protects the bridge if the round prices above \$10M while rewarding the earliest entry with interest. Both enter ahead of the markup a Series A would bring, quantified in the optimistic 2030 scenario below.

How the raise maps to the operating model. The 24-month projection deploys the full **\$1.0M** in three milestone-gated tranches: \$250K (April 2026, the bridge) funds the pilot, homologation, and the first three months; \$550-600K (July 2026) lands ahead of the \$400K scale-tooling window; \$150-200K (October 2026) seeds working capital as volume ramps. About \$95K of the plan is explicit contingency. **Han Hoang's \$100K founder capital sits alongside the bridge, outside the raise**, and is the cover for the minimum-cash dips shown in Runway & Minimum Cash. **Plan B is named, not implied:** if conversion runs slow (two consecutive months below 60% of planned deliveries), the October tranche is upsized or a \$500K extension is raised on seed terms; scale tooling is released only after Tier-1 price-fix contracts are signed.

Use of the \$1.0M Raise (Combined)

Scale & pilot tooling	\$420K
Team / OPEX (runway)	\$321K
Working capital service & deposit refunds	\$96K
Contingency / buffer	\$95K
Pilot production (10 units)	\$41K
Homologation, testing & certification	\$27K
Total Raise	\$1.0M (100%)

Optimistic Next Round: Series A (2030)

Round size	\$15M
Pre-money valuation	\$85M
Post-money valuation	\$100M
New Series A investor	15.0%
Seed Investor stake (post-A)	~5.8% \$5.8M paper ~7.7x
Bridge Investor stake (post-A)	~2.0% \$2.0M paper ~8.2x

What this shows: in the optimistic case, a 2030 Series A at a \$100M post-money values today's entry at roughly **7.7x for the Seed and ~8.2x for the Bridge** on paper, before any exit. Both convert at the same \$10M basis; the bridge edges ahead per dollar through its 6% accrued interest and earliest entry. This round also sets the dilution path: this Series A (15%) plus a later Series B (~23%) is what reduces the Seed and Bridge stakes to the exit levels used in the next section. Illustrative; an actual round depends on traction, terms, and market conditions. The Series A path and the Year 5 exit row are mutually exclusive timelines: a company raising at a \$100M post in 2030 is not also exiting at \$60M in 2030; read the exit table as the no-further-raise path.

Investment Structure, Returns & Cap Table

Two instruments fund the next phase, with founder capital alongside. The **Bridge Investor** puts in **\$250K now** for immediate use (pilot and homologation), structured as a convertible that converts at a **\$10M cap plus 6% accrued interest**: the cap protects the bridge if the round prices above \$10M, and the interest plus earliest entry is the reward for pre-pilot risk. **Han Hoang contributes \$100K of founder capital in the same window**, outside the raise. The **Seed Investor** puts in **\$750K at a \$10M pre-money valuation** (~\$11.0M post once the bridge converts). Both convert into the same priced round, so both show up on the post-seed cap table below. The chart and tables show what each investor owns and what they make on exit between **Year 5 and Year 7**. All exit figures are illustrative and assume the company actually reaches the stated valuation; they are not a promise of returns.

BRIDGE INVESTOR

\$250K → 2.4%

SEED INVESTOR

\$750K → 6.8%

NEW MONEY (THIS RAISE)

\$1.0M

POST-MONEY VALUATION

~\$11.0M

Exit Scenarios: Valuation and Investor Proceeds (Year 5 to Year 7)

Bridge Investor Returns (\$250K in, ~1.6% at exit)

Year 5 · \$60M exit	\$0.95M 3.8x
Year 6 · \$120M exit	\$1.91M 7.6x
Year 7 · \$200M exit	\$3.18M 12.7x

How the bridge compares: the \$250K converts at a **\$10M cap plus 6% accrued interest**, the same valuation basis as the seed. Its per-dollar edge comes from the interest and from entering first; if the seed prices above \$10M, the cap converts the bridge at \$10M and the discount appears automatically. The multiples run slightly above the seed's, honestly, not dramatically.

Seed Investor Returns (\$750K in, ~4.5% at exit)

Year 5 · \$60M exit	\$2.70M 3.6x
Year 6 · \$120M exit	\$5.39M 7.2x
Year 7 · \$200M exit	\$8.99M 12.0x

How to read it: proceeds = stake at exit × exit valuation; MOIC = proceeds ÷ amount invested. Stakes shown are after dilution from a future Series A and Series B (a combined ~34% dilution off the post-seed position).

Post-Seed Cap Table (after \$250K bridge + \$750K seed)

Gia Nguyen	35.2%
Han Hoang	26.4%
Hai Vo	17.3%
Tim Nielsen	11.8%
Seed Investor	6.8%
Bridge Investor	2.4%
Founders + Tim (combined)	90.8%

Assumptions: seed priced at \$10M pre-money, ~\$11.0M post once the bridge converts; the \$250K bridge converts at a **\$10M cap plus ~6% accrued interest** (~\$265K conversion amount), effectively the seed's price, with the cap protecting the bridge if the round prices higher. Figures shown before any employee option pool. A 10% ESOP carve-out is planned at or after seed and would dilute all holders proportionally.

Key Risks & Opportunities

The two things that can break the model, and the demand that can make it. On the left, a **BOM cost stress test**: run on the model's most exposed basis (Conservative fleet-only pricing, \$1,300 against a \$1,269 mid-scale all-in cost), BOM is ~93% of unit cost and the sub-\$1,000 target has not been formally quoted by Tier-1 suppliers, so even a 10% supplier or FX shock flips fleet-only margin negative. That is why supplier price-fixing, local sourcing, and the retail/accessory blend matter; at Base blended pricing the same stresses compress margin from 26% rather than erasing it. On the right, the **partnership coverage**: what each document actually commits, with no probability weighting applied.

BOM Cost Stress Test

Base, firm quotes hold (+0%)

+\$31/unit fleet GM

Mild stress (+10%)

-\$65/unit fleet GM

Severe stress (+20%)

-\$160/unit fleet GM

Worst case (+25%) **-\$208/unit fleet GM; mitigation: reprice fleet toward \$1,500 or lean on accessory and service margin**

Mitigation: 12-24 month price-fix contracts with Tier-1 suppliers post-pilot validation, local content ramp (reduce FX exposure), FX hedging via ACB facility, multi-source on commodity components (suspension, plastics, hardware).

Price stress: a forced fleet price of \$1,100 still clears \$133/unit against the \$967 Base cost and \$81/unit against the \$1,019 Conservative cost; below \$1,100 the plan shifts volume to co-development contracts rather than chasing list price.

Partnership Coverage, August 2026

Selex Motors	250-unit priority period (MOU)
Power-GOGO	MOU signed, revenue share unexecuted
Be Group	Fleet electrification MOU
Vertical food, industrial, smart cities	In discussion, unquantified
Committed volume (pre-sale block)200 units	

Near-term: there are no purchase orders. The near-term committed volume is the 200-unit pre-sale block, split 100 units to fleet operators at break-even pricing and 100 units through crowdfunding pre-order, financed by customers rather than equity. **Haircut view:** the MOU unit figures above are contractual thresholds and priority-period ceilings, not demand. Applying MOU-typical conversion of 30 to 50% to a pipeline with no signed PO produces a number that reads as forecast and is not one. Delivering the 200-unit block with fleet operating data is what converts these MOUs into orders. Long-term: HCMC targets full conversion of a roughly 400,000-driver fleet by end 2029, which is the regulatory tailwind, not a company projection.

Use of Bridge Capital: \$250K (Immediate)

The **Bridge Investor's \$250K** is for immediate use and is deployed in two short phases, with **\$100K of founder capital from Han Hoang** committed in the same window, lifting bridge-phase capital to \$350K. **Phase 1** funds the pilot (tooling, a first batch of units, homologation, and runway) to prove the product and convert MOUs. **Phase 2** deploys the remainder toward early scale-up and working-capital seeding once the pilot validates demand. Capital is released against milestones, not all at once. The \$750K seed deployment is shown in the next section.

Use of Seed Capital & 5-Year Deployment

Where the money goes over five years. The **\$750K seed** (plus the bridge and founder capital) funds Years 1 and 2: getting to a validated pilot and early production. From Year 3 on, deployment is funded primarily by operating revenue plus a planned **Series A**, and the dominant line item becomes working capital, because a hardware business ties up cash in inventory and supplier terms as volume scales. The chart shows total capital deployed by year and category; the table shows how the \$750K seed is allocated up front.

Capital Deployment by Year and Category (5-Year View)

Funding sources: Years 1-2 (~\$3M total need) are covered by the \$1.0M raise, the \$100K founder capital alongside it, plus early revenue and customer deposits; Years 3-5 scale (~\$37M cumulative) is funded by operating cash flow and a planned Series A. Figures are illustrative annual deployment, not committed budgets.

Allocation of the \$750K Seed (Up-Front)

Scale tooling & engineering	\$400K
Operations / team (post-pilot OPEX)	\$230K
Certification & working capital	\$73K
Contingency	\$47K
Total Seed Deployed	\$750K (100%)

Closing Statement

The bottom line: why these numbers add up to a business worth backing.

Volty U1 is a deliberately unglamorous bet: a low-margin, high-volume utility vehicle aimed at the part of the market that is actually electrifying first, the fleets.

The model in this dashboard does not rely on a pricing miracle or a premium-brand halo. It works because the unit economics are real at a \$1,300 fleet price, because the capital required to reach break-even is measured in hundreds of thousands rather than millions, and because the demand is being pulled forward by regulation rather than marketing. The multi-network battery strategy keeps the operator relationship with NUEN MOTO rather than with the energy provider, and the capital-light partnership structure means infrastructure cost sits with the battery networks, not with NUEN MOTO.

The honest risks are named here, not hidden: a thin gross margin that a BOM or FX shock can erase, and a per-unit working-capital gap that has to be financed as volume scales. Both are quantified, both have mitigation paths, and both are the right problems to have for a company whose constraint is demand conversion, not demand itself.

The \$250K bridge is sized to prove the pilot and convert the signed and in-progress pipeline into deployed units; the \$750K seed funds the move from pilot to early production. Everything beyond that is a financing and execution question, not a product question. The product case is made.

Dashboard Guide

A quick orientation for first-time readers. Four habits make the rest of the dashboard make sense: switch scenarios, read the charts in sequence, sanity-check the unit economics, and watch the working-capital gap.

How to Use This Dashboard

Switch Scenarios

Click the scenario buttons (Conservative, Base, Optimistic) to see how unit volume, growth rate, and timing impact cash flow, break-even, and profitability.

Check Unit Economics

At scale (Base), all-in cost is \$967 against a \$1,200 fleet / \$1,350 blended price, \$383/unit blended margin (~26%). The stress test shows BOM increases from supplier or FX volatility on the most exposed (Conservative fleet-only) basis.

Read the Charts

Revenue starts month 9 (Dec 2026) and ramps with fleet conversions. EBITDA is positive from Q4 2026 (Base); full break-even lands month 14. OPEX scales with headcount phases. Break-even spans months 10-18 by scenario.

Track Working Capital

The ~\$478 figure is the day-60 supplier balance paid with no offsetting inflow for 35 days. The net cumulative position per unit troughs at about \$283 across the full cycle. Size the facility on the \$478 outflow, not the \$283 net.

NUEN MOTO Volty U1 Financial Dashboard v1.6.1 | Built May 2026, reconciled to model v1.6.1 in June 2026, reviewed August 2026 without re-anchoring the projection start date or capital structure. Section sources: Assumptions & Inputs, Scenario Analysis, Unit Economics, BOM Sensitivity, Break Even Analysis, Profit & Loss, Tax & CIT Schedule, Cash Flow Projection, Operating Expenses, Headcount Roadmap, S&M Scaling, Working Capital Cycle, Customer Pipeline, Use of Funds, and Investor Returns sheets.

This dashboard is for internal use and investor presentations. All projections are based on the model pricing set (\$1,200 fleet Base, \$1,300 fleet Conservative, \$1,500 retail), the confirmed OPEX baseline (\$24K/month Phase 0 payroll within \$34.7K/month total), and partnership coverage as documented rather than probability-weighted. The independent stress-test flags (BOM sensitivity, working capital realism, CIT treatment) are fully addressed in the underlying model tabs.
